Running Title: Decontaminating N95 masks with UVGI

Abstract

Background: Inadequate supply of filtering facepiece respirators (FFR) for healthcare workers during a global pandemic such as the novel coronavirus outbreak (SARS-CoV-2) is a serious public health issue.

Aim: To synthesize existing data on the effectiveness of ultraviolet germicidal irradiation (UVGI) on N95 FFR decontamination.

Methods: Systematic review (PROSPERO CRD42020176156) on UVGI in N95 FFRs using Embase, Medline, Global Health, Google Scholar, WHO feed, and MedRxiv. Two reviewers independently determined eligibility and extracted predefined variables. Original research reporting on function, decontamination, or mask fit following UVGI were included.

Findings and Conclusions: Thirteen studies were identified, comprising 54 UVGI intervention arms and 58 N95 FFR models. FFRs consistently maintained certification standards following UVGI. Aerosol penetration averaged 1.19% (0.70-2.48%) and 1.14% (0.57-2.63%) for control and UVGI arms respectively. Airflow resistance for the control arms averaged 9.79 mm H₂O (7.97-11.70 mm H₂O) vs 9.85 mm H₂O (8.33-11.44 mm H₂O) for UVGI arms. UVGI protocols employing a cumulative dose >20,000 J/m² resulted in a 2 log reduction in viral load. A >3 log reduction was observed in 7 UVIG arms using >40,000 J/m². Impact of UVIG on fit was evaluated in two studies (16,200; 32,400 J/m²) and did not find evidence of compromise. Our findings suggest that further work in this area (or translation to a clinical setting) should use a cumulative UV-C dose of 40,000 J/m² or greater, and confirm appropriate mask fit following decontamination.

Keywords: PPE, Decontamination, Masks, N95, UVGI

Introduction

The global spread of the novel coronavirus (SARS-CoV-2) threatens public health worldwide, and healthcare professionals are at an increased risk due to their close contact with infected patients. Physicians have reported that NIOSH-certified N95 filtering face respirators (FFRs), which filter 95% of airborne particles[1], were the personal protective equipment (PPE) that they felt protected them most during the last serious coronavirus outbreak in 2003 (SARS-CoV-1)[2]. Correspondingly, N95 FFRs are currently recommended by the U.S. Centers for Disease Control and Prevention (CDC) to be donned by healthcare professionals treating patients with the coronavirus disease (COVID-19)[3]. Unfortunately, PPE shortages are characteristic of large epidemics, and COVID-19 is no exception[4,5]. Consequently, rationing FFR supply has become a matter of increasing urgency at many hospitals worldwide.

A potential approach to extending the use of existing FFRs would be to decontaminate and re-use the masks. This has prompted the question of whether FFRs can be safely decontaminated for reuse without compromising their structural integrity and efficacy[6]. Previously studied FFR decontamination methods have included bleach, ethanol, hydrogen peroxide, autoclaving, microwaving, and UV light[7-9]. Ultraviolet germicidal irradiation (UVGI) using shortwave ultraviolet-C light (UV-C, usually 245 nm) has a long history of antiseptic applications in medicine and is used for air disinfection in hospitals[10]. Recent reviews highlight the growing popularity of UV-C light for microbial decontamination of objects from toothbrushes to stethoscopes[11-13], and its scalable nature makes it suitable for large-scale decontamination during a pandemic. However, any decontamination process may limit the

functionality of the mask if it alters its fit, filter efficiency (aerosol penetration), and/or airflow resistance[14]. Therefore, while some institutions have already implemented UVGI FFR-decontamination protocols during the COVID-19 pandemic[15], FFR producers continue to recommend disposal of contaminated FFRs due to the lack of an evidence-based protocol that addresses these important functional parameters[16].

To help inform FFR-reuse policies and procedures, our team has conducted three systematic reviews to synthesize existing published data regarding the effectiveness of UVGI, heat, microwave irradiation, and chemical disinfectants for N95 FFR decontamination. This review will focus on UVGI, with the following objectives: (1) to assess the impact of the UVGI method on FFR performance, with a specific focus on aerosol penetration and airflow resistance; (2) to determine the effectiveness of the UVGI decontamination method at removing viral or bacterial load; and (3) to describe measures or observations related to fit or physical degradation.

Methods

Study protocol and objectives were established a priori and registered on PROSPERO on 25th March 2020 (CRD42020176156), and reported here according to the PRISMA guidelines of systematic reviews (Appendix A)[17]. The protocol was also uploaded as a pre-print to OSF on 29th March 2020 (<https://osf.io/238yh/>).

Eligibility Criteria

Studies were eligible for inclusion in this systematic review if they satisfied all of the following criteria: (1) Original publication or systematic review; (2) Study reported on decontamination procedures for N95 (including SN95) filtering facemask respirators or their

components; (3) At least one of the decontamination procedures evaluated used ultraviolet light; and (4) The study reported on at least one of the following outcomes of interest: (i) effectiveness of the UVGI method at removing viral or bacterial load; (ii) impact of the UVGI method on filtering face mask performance, with a specific focus on aerosol penetration and airflow resistance (pressure drop); or (iii) measures or observations related to change in mask fit or physical degradation of the mask following UVGI exposure. Only studies published in English or French were included. Studies published prior to 1972, the year that the N95 FFR was invented, were excluded. We also excluded editorials, narrative reviews, book chapters and patents.

Search and Selection

The following databases were searched by two health sciences librarians (LS and MS) during the electronic component of the systematic review: Medline (1946- March 22, 2020) and Embase (1947—March 22, 2020) through the Ovid interface and Global Health (1913-March 20, 2020) via CAB Direct. A search strategy was developed in Medline, reviewed and then translated into the other databases (Appendix B). There were no language exclusion criteria, nor any other publication restrictions. Google Scholar was searched (March 24, 2020). The COVID-19 search concept was adapted from search developed by Wichor Bramer and posted on Search blocks/Zoekblokken (<https://blocks.bmi-online.nl/catalog/397>, visited March 18, 2020). This yielded 2960 hits. The first 1000 were harvested using Publish and Perish and records were reviewed in order of relevance until a series 50 consecutive apparently irrelevant records was reached. This generated a set of 208 records, which was then exported to EndNote. The World Health Organization (WHO) COVID-19 record set posted March 23, 2020 was downloaded from <https://www.who.int/emergencies/diseases/novel-coronavirus-2019/global-research-on-novel->

coronavirus-2019-ncov. The records were imported into Reference Manager, where topical queries were performed. References from all searches were then entered into an Endnote file and duplicate records were removed.

Citation screening and data extraction

Titles and abstracts were then uploaded to InsightScope (www.insightscope.ca) for title and abstract screening and full text review. At both title/abstract and full text review, citations were assessed in duplicate and independently. To allow for rapid completion of the systematic review task, the assessments were performed by a team of 13 reviewers recruited from the University of Ottawa, University of Manitoba and McMaster University. Each reviewer was asked to read the protocol and complete a qualification or test set of size 50 citations (6 true positives, 44 true negatives), and were required to achieve a sensitivity in excess of 80%. Of the reviewers eight (62%) correctly identified all 6 true positives, with the remaining 5 (38%) correctly identifying 5. At both title/abstract and full text review, records were removed only if both reviewers agreed it to exclude. Those cases with conflicts were resolved by review by the study lead (JDM) or co-investigator (KO). At the completion of full text review the study lead reviewed the eligible citations to identify potential duplicates and confirm eligibility. A data extraction tool was developed in REDCap[18,19] by the study lead (JDM) and piloted by co-investigator (KO) on five eligible studies. Eligible studies were divided equally among the reviewers for duplicate, independent data extraction, followed by conflict resolution by a third co-investigator (JDM, KO).

Outcome data is reported for N95 (particulate or surgical) masks or their components only. Other N95 masks (e.g. R or P) were not included in the analysis. “Components” was defined as a piece of an N95 mask that had been cut out with all layers still intact. When

investigators separated out the layers of an N95 mask and reported outcomes for each individual layer, this data was not included in the analysis but was reported descriptively in the results.

When authors did not report the UV-C dose, but reported intensity and time, UV-C dose was calculated. Preference was always given to the actual UV-C dose administered versus the target UV-C dose. In cases where authors only reported the target dose, but did report the intensity and time administered, administered UV-C dose was calculated. For ease of reporting, all doses were converted to J/m². When necessary, data was extracted from figures using SourceForge Plot Digitizer (<http://plotdigitizer.sourceforge.net/>).

Study analysis and Statistics

All statistical analysis were performed using the R statistical programming language[20]. Data was meta-analyzed using a random effects model with the R package ‘meta’[21]. Random effects meta-analysis were employed to present either the pooled absolute value pre / post UVGI or relative change (from control or no treatment arm).

For both the particle penetration and airflow resistance outcomes the data was presented as an absolute value. Appropriateness of pooling was assessed by examining studies heterogeneity using an I² statistic. Lindsey *et al*[22] had one more than one UVGI intervention arm and out of concern that this one experimental paradigm might contribute disproportionately to our data and to reduce within study variation, we took a conservative approach of only including this study’s highest dose experiment. For the outcome UVGI decontamination, all but one study was on viruses; to improve comparability the one study on bacteria decontamination was removed. Significant heterogeneity was seen with the methods and outcomes related to contamination and decontamination. To account for differences in methods (viral load, application and retrieval from mask) we reported pooled results using log change. For studies

which did not report log change, values were calculated based on the data provided. The average log change was taken across mask types within the same dose and medium. (in addition to absolute value or change). For the viral load log change, standard error was missing in 20% of study arms. To minimise bias, we imputed standard error for these cases, by substituting the average standard error of all study arms (NB: modeling the missing data was disregarded due to poor predictability). Again, prior to pooling the results we performed a test of statistical heterogeneity using I^2 tests. Random effects meta-analysis was used. In the evaluation of UVGI and germicidal activity we also characterised the influence cumulative dose of UV light (Joules per m^2 (J/m^2))

Risk of Bias and Quality Assessment

Risk of bias was ascertained at the study level. The following factors were determined *a priori* as supportive of low risk of bias: (1) Application of UVGI procedures to masks from the same lot to minimize lot-to-lot variation; (2) Controlled study or pre/post study design; (3) Application of identical study procedures between arms other than intervention; and (4) Outcome evaluators blinded to study arm or outcome evaluated objectively (result provided by a machine). Based on the anticipated small size of the available literature (<10 studies) and limited variability in study sample sizes generally observed in laboratory studies, no statistical test of publication bias was planned. The cumulative body of evidence regarding the application of UVGI for decontamination and reuse of FFR was evaluated using the following criteria: (1) UVGI was shown to: (1) achieve established thresholds for success for pathogen decontamination (≥ 2 log reduction) and function (National Institute for Occupational Safety and Health (NIOSH) standards for airflow resistance and aerosol penetration); (2) these findings were demonstrated consistently (≥ 2 studies); (3) without failing in any other study.

Results

Identification of Eligible Studies

In total, 1326 records were identified through the initial database search, resulting in 1108 records for screening following de-duplication in Endnote. Title and abstract screening excluded 1053, with the review team achieving a kappa of 0.5. At full text level the reviewers excluded 40 of the records, with a kappa of 0.95. Review of the 15 remaining records by the study lead identified two as duplicates, and two records, a thesis and a government report, that were different reports of the same studies. Of the remaining 11, one study (Jinadatha, 2015)[23] was deemed ineligible during data extraction as only the plastic portion of the facemask was used in the evaluation of UVGI decontamination, and neither of the other two outcomes (aerosol penetration, airflow resistance) were considered. Three additional eligible studies were identified on review of the references lists of the retained studies. An overview of the search process, results and reason for exclusions are shown in the PRISMA diagram (Figure 1).

Study Demographics

Geographically, 12 studies were performed in the United States, with the remaining publication originating from East Asia. The studies included 54 total UVGI arms, with a range of 1 to 22 arms per study. A summary of the included studies is provided in Table I. The studies included a total of 58 N95 masks (average 4.5) with a range of 1 to 15 evaluated per study. The most common N95 mask types were 3M 1860 (n=5), 3M 1870 (n=5) and 3M 8210 (n=3). In four studies, representing 13 of the 58 masks, the N95 brand was not specified[7,9,24,25]. Table I shows the masks evaluated in each study. The number of studies evaluating the 4 main study

outcomes were: particle penetration (n=5), airflow resistance (n=3), germicidal activity (n=7) and impact on physical characteristics/fit (n=6).

Particle Penetration and airflow resistance

There were five studies identified that evaluated particle penetration post UVGI[9,22,24-26] (Table II). Four of the studies evaluated a single UVGI protocol, with Lindsley *et al*[22] having 5 UVGI intervention arms. The particle penetration in masks were on average 1.19%% (ranging from 0.70-2.48%) and 1.14% (ranging from 0.57-2.63%) for the control and post UVGI treatment arms, respectively. None of the individual studies average mean difference post UVGI treatment were statistically discernable from zero (Figure 2). Further the random effects meta-analysis (that weights the evidence by the size of the study) calculated a mean difference of -0.09% (95% CI -0.21-0.04; Figure 2). Statistical heterogeneity was low with an I-squared of ~0%. Fisher *et al* reported aerosol penetration for the individual layers of 6 N95 FFR models[27]. The filter efficiency of the individual filtering layers examined ranged from 87.2 to 99.5% following UVGI. The majority of filter layers had an efficiency of >94%.

Three studies evaluated airflow resistance [22,24,25] (Table III). Two of the studies evaluated a single UVGI protocol, with Lindsley *et al* evaluating 5 UVGI intervention arms (NB: only the highest dose arm was included in our meta-analysis). The airflow resistance in masks were on average 9.79 mm H₂O (ranging from 7.97-11.70 mm H₂O) and 9.85 mm H₂O (ranging from 8.33-11.44 mm H₂O) for the control and post UVGI treatment arms, respectively. None of the individual studies average mean difference post UVGI treatment were statistically discernable from zero (Figure 2). The random-effects meta-analysis calculated a mean difference of 0.03% (95% CI -0.47 – 0.54; Figure 2). Statistical heterogeneity was low with an I-squared of

~0%. Fisher *et al* (2011) reported airflow resistance for the individual layers of 6 N95 FFR models[27] following UVGI. The airflow resistance of the individual filtering layers ranged from 2.5 to 7.6 mm H₂O.

Germicidal

Seven studies evaluated the germicidal impact of one or more UVGI interventions[7,8,26-30], including one study on bacteria, and 5 studies on viruses (Table IV). The most common were H1N1 and MS2, used as the viral pathogen in two studies each. Lin *et al* was the only group to use a bacterial pathogen. Using a water medium, they looked at the relative survival of *Bacillus subtilis* prototype strains following exposure to a range of UV-C doses from 11,340 to 226,800 J/m². Relative survival following UVGI was 0.8 ± 0.4 for the lowest dose, 0.2 ± 0.14 for the second lowest dose, and 0 ± 0 for the three higher doses.

One mask was removed from the viral analysis as an outlier. Fisher *et al* reported a log reduction in viral load of 0.1 ± 0.2 for the Cardinal N95-ML in contrast to 2.9 ± 0.2 and >4.8 for the other masks they evaluated[27]. The low log reduction for the Cardinal N95-ML was attributed to a high-shielding outer mask layer that limited the amount of UV-C that reached the filter layers of the mask. Collapsing the viral studies (see Methods) resulted in 30 different UVGI arms, evaluating doses ranging from 1,500 to 72,000 m/J² (Table V). 53% (n = 16) of UVGI arms used a water medium vs. 47% (n = 17) who used another medium such as beef extract, 271B, or artificial saliva. All fifteen UVGI arms that administered a cumulative dose $>20,000$ m/J² observed a ≥ 2 log reduction in viral load compared to 73% (n = 11) of the 15 UVGI intervention arms that administered a cumulative dose $<20,000$ m/J². The average log reduction for the UVGI intervention arms that administered a dose above or below 20,000 J/m² was $3.61 \pm$

0.99 and 3.14 ± 1.09 respectively. A ≥ 3 log reduction was observed in 73% ($n = 11$) of UVGI arms administering a dose $>20,000 \text{ J/m}^2$ and 86% ($n = 7$) of UVGI arms administering a cumulative dose $>40,000 \text{ J/m}^2$. The average log reduction when using a dose $>40,000 \text{ J/m}^2$ was 3.74 ± 0.98 . The exploratory Figure 3 suggests that the cumulative UVGI dose seems to have a greater effect on viral load in those lab trials where the viral particles were applied to the mask not using water. If mask performance in a clinical practice environment is more similar to the non-water medium (because organic matter and viral particles are found on masks), then the intensity of the UVGI light may affect the decontamination process.

Physical characteristics

Six studies were identified that evaluated some aspect of change in physical appearance and odor[7,9,24,25,31,32] or fit[31,32] (Appendix C). All six studies assessed physical appearance using visual inspection, with one study also performing a manual inspection for changes in texture and feel[9]. Three studies evaluated change in odor by sniffing the FFRs post-UVGI exposure[9,25,31]. Viscusi *et al*[31] also determined subjects' perception of odor strength using a visual analog scale. There were no significant changes in physical appearance, texture or odor to any mask model following UVGI exposure.

Only two studies assessed fit. Viscusi *et al* performed an eight exercise standardized fit test pre-UVGI exposure, followed by a multi-donning fit test post-UVGI exposure[31]. A multidonning fit factor (MDFF_{10}) was calculated as the harmonic mean of the 10 FFs resulting from the replicate multidonning fit test sessions. FF was the Fit Factor calculated by the PORTACOUNT Fit Tester as the ratio of the ambient particle concentration outside the respirator compared with the particle concentration inside the respirator. The MDIFF_{10} value

following UVGI treatment was favourable. The average MDIFF₁₀ value following UVGI treatment was 138.3 ± 28.5 versus 142.7 ± 27.2 for control. None of the 6 masks showed a statistically significant difference in MDIFF₁₀ between arms. The strap of one FFR treated with UVGI broke during the multi-donning fit test, compared to straps from 3 FFRs in the control group. Bergman *et al*[32] used a similar approach but employed 1, 2 and 3 cycles of UVGI on three different N95 models. Three cycles of UVGI did not cause significant changes in mask fit. The passing rate for the 3M 1860 was 95%, 100% and 100% after 1, 2 and 3 cycles respectively. The passing rate for the 3M 1870 was 100% after 1, 2 and 3 cycles. The passing rate for the KC PFR95-270 (46767) was 95%, 95% and 90% after 1, 2 and 3 cycles.

Other Evaluations

Lindsley *et al*[22] evaluated the strength of FFR straps following UV-C exposure. The breaking strength of the respirator straps decreased after UVGI exposure compared to paired controls by 10-21% (UV-C dose 590 J/cm²) to 20–51% (UV-C dose 2360 J/cm²). Viscusi *et al*[31] evaluated subject experiences on perceived donning ease and FFR comfort following UVGI exposure using a visual analog scale, as well as responses to an open-ended statement, “Tell us something about this respirator”. Donning ease and FFR comfort was not affected by UVGI, and no distinct patterns were identified in the open-ended comments.

Risk of Bias

Studies were assessed for Risk of Bias. All of the study designs included an untreated or control arm for comparison. Six studies[9,22,24,25,31,32] reported that the N95 FFRs all came from the same lot, and nine studies[7-9,24,26,28,30-32] stated that laboratory conditions were identical between intervention arms. No studies reported that outcome assessors were blinded,

however, the subjects participating in the fit testing in Viscusi *et al*[31] were blinded to whether they were evaluating an FFR from the control or intervention arm. There was uncertainty regarding the risk of bias for the germicidal outcomes, as it was not clear whether the individuals performing the evaluations were blinded to treatment arm and/or UVGI dose. The outcome measures related to mask function were evaluated objectively (i.e. aerosol penetration, airflow resistance measured using a machine). (Appendix D).

Discussion

This is the first systematic review to synthesize the existing evidence on decontamination of N95 FFRs using UVGI. We found that a single cycle of UVGI with UV-C light does not affect N95 FFR performance, and was able to decontaminate mask surfaces exposed to viruses in laboratory conditions without significant changes in FFR appearance or odor. We observed that level of decontamination was associated with cumulative UV dose and the conditions used to simulate viral spread, specifically the addition of salts and biological particulate (saliva and protein). The limited body of evidence evaluating UVGI impact on physical characteristics and fit did not present evidence of negative effects

This systematic review identified 5 studies that reported on changes in aerosol penetration following UVGI. NIOSH has established a 95% filter efficiency standard (i.e. a filter penetration of <5%) for N95 FFR[14]. All five studies that reported on aerosol penetration adhered to NIOSH testing standards, using a NaCl aerosol with a particle size of 300nm. Results showed minimal change in filter efficiency following the application of multiple different UVGI protocols on a variety of FFR models, and all FFRs evaluated maintained the standard filter

efficiency of $\geq 95\%$. A recent report from N95 FFR manufacturer 3M on N95 decontamination and reuse emphasizes the critical importance of ensuring the decontamination method does not compromise filter performance[16]. The report also includes the results of an internal study which found that 3M N95 FFRs maintained a filter efficiency of 95% following repeated UVGI exposure (5-10 UV-C cycles), however they did not provide sufficient information to calculate a cumulative UVGI dose. In addition to standards for filter efficiency, NIOSH has also established standards for airflow resistance of N95 FFRs. Testing is performed using a filter tester at 85 L/min of constant airflow, and to meet certification requirements, N95 FFRs must demonstrate a peak average inhalation of 35 mm (343.2 Pa) and an exhalation resistance to airflow 25 mm (245.1 Pa) H₂O pressure[33]. This systematic review found three studies that evaluated airflow filtration using standardized testing protocols following UVGI. None of the seven FFRs evaluated across the three studies demonstrated significant changes in airflow filtration following UVGI, and all FFRs maintained the NIOSH airflow standards.

Mask fit is another important consideration, as improper fit results in an inadequate seal of the mask against the wearers face, reducing the mask's ability to prevent particle penetration[34]. Fit testing is performed according to the Occupational Safety and Health Administration (OSHA) respiratory protection regulation using a PORTACOUNT Fit Tester to determine the volume of test substance that is leaking into the mask. Only two papers were identified that evaluated FFR fit following UVGI exposure. While the results from Viscusi *et al*[31] and Bergman *et al*[32] showed no significant change in mask fit following UVGI, they both used a modified version of the OSHA fit testing protocol following UVGI decontamination. Further, the fit testing was not performed in real world conditions. Therefore, the evidence regarding the effects of UVGI on FFR fit is limited. Further investigation using additional UVGI

protocols and mask models in a clinical setting is required in order to confirm whether or not UVGI alters the fit of N95 respirators.

The six studies that evaluate on changes in mask appearance following UVGI did not report any significant changes in physical appearance or odor following a single cycle of UVGI exposure[7,9,24,31], a single continuous exposure equivalent to 3 cycles of UVGI[25] or 3 cycles of UVGI[32]. This is in contrast to the report by 3M, who observed physical degradation of their FFRs following 5 to 10 cycles of UVGI. As a result, 3M still does not recommend decontamination and reuse of N95 FFRs at this time[16]. It is likely that the physical observation observed by 3M was due to the number of UVGI cycles employed. Therefore, there may be a limit on the number of UVGI cycles that can be applied to a given FFR before the mask begins to breakdown. Further, there is evidence that mask fit deteriorates through repeated donning and doffing[35] but with careful donning, 5 safe reuses appear possible[36]. The number of decontamination and re-use cycles that can be applied to a FFR will be limited by breakdown imposed by both UVGI and donning and doffing.

While maintaining the function and fit of the FFR critically, an equally important metric for evaluating UVGI protocols is their ability to eradicate infectious material from the mask surface. The seven studies that reported on decontamination demonstrated that exposure to UV-C light can significantly reduce the number of viable viral pathogens from N95 FFR, with cumulative doses of $>20,000 \text{ J/m}^2$ and $>40,000 \text{ J/m}^2$ consistently resulting in log reductions of ≥ 2 and ≥ 3 respectively. However, it is important to note that these evaluations were all performed in a laboratory setting and do not represent real world conditions. There is rationale to suggest that the decontamination effect of UVGI could actually be more effective in the real world setting. Mills *et al* overloaded the mask surface with more virus than would be observed

following a real life contamination event, yet still observed ≥ 3 log reduction in viral load on 12 of the 15 masks evaluated[28]. Of note, the fact that a significant reduction was not observed in all 15 masks suggests that mask model and material should be considered as factors that may influence the success of UVGI decontamination. For example, Fisher *et al* reported a log reduction of 0.1 ± 0.2 for the Cardinal N95-ML in contrast to 2.9 ± 0.2 and >4.8 for the other masks evaluated[27], which was attributed to a high-shielding outer mask layer that limited the amount of UV-C that reached the filter layers of the mask.

Additional evidence that decontamination may be more effective in the real world setting comes from the time elapsed between UVGI and measurement of pathogens in the studies examined. The majority of authors measured pathogen levels immediately following UVGI decontamination. The one study by Lin *et al* that measured bacterial levels immediately after, and 24 hours after, UVGI found that bacterial levels were further reduced by 24 hours[8]. This is despite the fact that the mask material was stored in worst-case temperature (37°C) and humidity (95% RH) conditions for the 24 hour period. It is well established that bacteria and virus levels on surfaces decrease over time[37,38]. In the real world setting, FFRs undergoing UVGI decontamination could be allowed to sit for an extended period of time (e.g. 24 hours) prior to re-use, in order to further enhance the decontamination process. Regardless of the UVGI protocol ultimately selected, a recent study of SARS-CoV-2 persistence on a variety of surfaces showing, at minimum, a one log decline in infectivity every 24 hrs suggests that, where possible, a one week holding period for respirators following decontamination will materially decrease risk of viral persistence[39].

Overall the evidence demonstrating that N95 FFR performance is maintained following a single cycle UVGI can be classified as strong. Findings were consistent across multiple studies,

aerosol penetration and airflow filtration are measured objectively, and all studies that reported on FFR function used a control arm in their study design. The evidence regarding the effectiveness of UVGI to decontaminate mask material is less strong. Although findings were also consistent across studies and a control group was always incorporated into study design, outcome assessors were not blinded. Further, the existing evidence is all laboratory based, and is not reflective of real world conditions. Data regarding the effect of UVGI on FFR fit is limited, thus it is not possible to definitely conclude whether or not this method of decontamination alters the fit of N95 masks.

Based on the available evidence, we recommend a cumulative dose of no less than 20,000 and ideally 40,000 J/m² be used for clinical application of UVGI and/or further investigation. The 40,000 J/m² cumulative dose consistently resulted in ≥ 3 log reduction in viral pathogens. Modelling derived by Fisher *et al* for influenza contamination of FFRs from aerosol sources showed full decontamination would require a log reduction of 3[40]. In addition, this dose has been shown to not alter FFR performance (particle penetration, airflow resistance). Data from one study that evaluated mask fit following a comparable dose of UVGI (32,400 J/m²) showed no change in mask fit, but additional investigation would be prudent.

Limitations

Although this systematic review provides valuable information regarding the possibility of UVIG decontamination for the safe reuse of FFR, a number of limitations must be acknowledged. Each study used a different combination of mask types. In order to address this we aggregated across mask types within each study, treating the pooled replicates across mask types as our statistically independent sampling unit. This is appropriate for our research question aimed at performance of FFRs in general (where we assume little difference between mask

types). If there are large differences between mask types, our approach might artificially inflate our sample size; if this were the case it would unlikely change our findings, due to the consistency of these studies conclusions and low heterogeneity.

Conclusions

The function of N95 masks, based on aerosol penetration and airflow filtration, is maintained following a single cycle of UVGI. Decontamination using UV light in the laboratory setting suggests that this can be a successful method of removing infectious pathogens from FFRs. Future studies should use a cumulative UV-C dose of 40,000 J/m² and focus on validating the effectiveness of UVGI decontamination in the real world setting, and on determining the impact of UVGI on mask fit.

Figure 1: PRISMA Flow Diagram

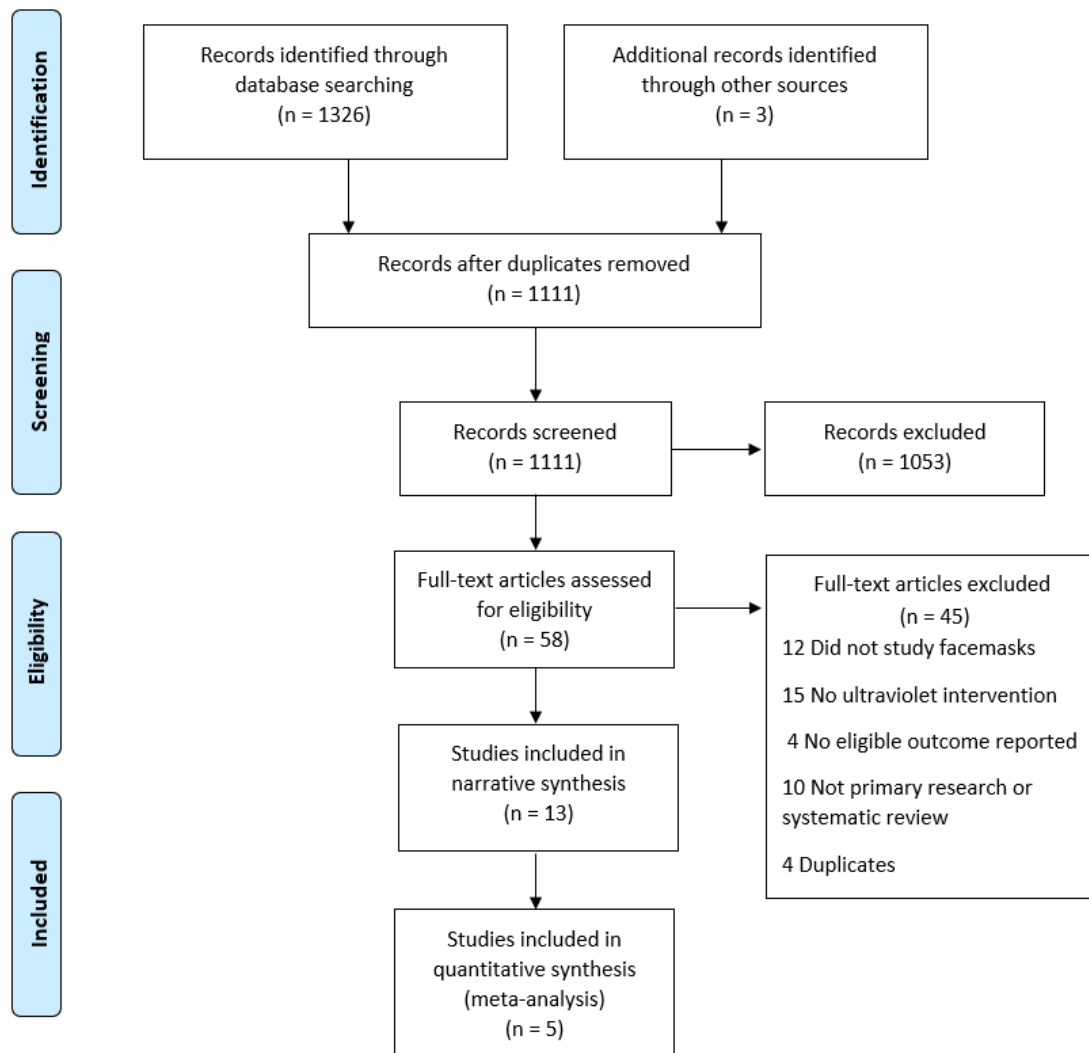

Figure 2: Pooled Results assessing Particle Penetration and Airflow Resistance.

The forest plot in A illustrates the mean particle penetration in masks. The experimental arm refers to the UVGI - Ultraviolet germicidal irradiation, treated arm. Mask type examined varied by study; Bergman *et al* (N95-A,N95-B,N95-C), Lindsley *et al* (3M 1860, 3M 9210, GE 1730,KC 46727), Lore *et al* (3M 1860, 3M 1870), Viscusi *et al* 2007 (N95), and Viscusi et al 2009 (N95-A,N95-B,N95-C). The forest plot in B illustrates the mean airflow resistance in masks. The experimental arm refers to the UVGI - Ultraviolet germicidal irradiation, treated arm. Mask type examined varied by study; Bergman *et al* (N95-A, N95-B, N95-C), Viscusi *et al* 2009 (N95-A, N95-B, N95-C) and Lindsley *et al* (3M 1860, 3M 9210, GE 1730, KC 46727). Total refers to the number of replicates per mask.

Figure 3: Ultraviolet germicidal irradiation cumulative dose by log change in viral load in trials that used a water versus a non-water medium

Scatter plot showing the relationship between the cumulative UVGI dose (J/m^2) and viral load log change post UVGI. The two horizontal panels represent the medium (or solution) in which the viral particles were applied to the face mask, for these lab trials. Note, this is a descriptive plot and not a meta-regression.

Appendix A – PRISMA Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	6
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	6
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	6-7
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	7-8
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Appendix B
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	8
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	8-9
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	8-9

Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	10
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	9
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I^2) for each meta-analysis.	9-10
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	10
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	described in the protocol
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	39, Figure 1
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Table 1
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	Appendix D
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Figure 2 Figure 3
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	12-14
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	15
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	n/a
DISCUSSION			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	18-20

Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	20
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	20-21
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	23

WHO database

The entire record set of March 23, 2020 was downloaded from <https://www.who.int/emergencies/diseases/novel-coronavirus-2019/global-research-on-novel-coronavirus-2019-ncov> into Reference Manager and then all indexed and non-indexed fields were searched using these query strings:

Ultraviolet} or {ultra violet} or {ultra-violet} or {UV} or {UVGI} or {germicidal irradiation} or {decontamin*}

AND

{respiratory protective device*} or {mask*} or {face shield*} or {n95} or {n-95} or [32] or {ffrs} or {filtering face*}

Appendix C: Assessment of fit and physical appearance of N95 FFRs following UVGI exposure

Table C.1- Physical Appearance and Odor

Author, Year	UVGI Intervention	N95 Masks	Method of Assessment in Change in Physical Appearance or Odor	Changes following UVGI Exposure
Bergman, 2010	Wavelength (nm): 254	N95-A	Visual inspection for changes in physical appearance	No significant changes
	Watts (W): 40 Duration (min): 45 Dose (J/m ²): 48,600 Intensity (mW/cm ²): 1.8 Distance (cm): 25	N95-B N95-C SN95-D SN95-E SN95-F	Changes in odor by sniffing the mask	No significant changes
Bergman, 2011	Wavelength (nm): 245	3M 1860	Visual inspection for changes in physical appearance	No significant changes
	Watts (W): 40 Duration (min): 15 Dose (J/m ²): 16,200 Intensity (mW/cm ²): 1.8 Distance (cm): NR	3M 1870 KC PFR95-270 (46767)		
Heimbuch, 2011	Wavelength (nm): 254	N95 models (n=3) not specified	Visual inspection for changes in physical appearance	No significant changes
	Watts (W): 80 Duration (min): 15 Dose (J/m ²): 14,400 – 59,400 Intensity (mW/cm ²): 1.6 – 2.2 Distance (cm): 25	SN95 models (n=3) not specified		
Viscusi, 2007	Wavelength (nm): 254	N95 model (n = 1) not specified	Visual inspection	No significant changes
	Watts (W): 40 Duration (min): 30 – 480 Dose (J/m ²): NR Intensity (mW/cm ²): NR Distance (cm): NR			
Viscusi, 2011	Wavelength (nm): 245	3M 8000	Visual inspection for changes in physical appearance	No significant changes
	Watts (W): 40 Duration (min): 30 Dose (J/m ²): 32,400 Intensity (mW/cm ²): 1.8 Distance (cm): NR	3M 8210 Moldex 2200 3M1860 3M1870 Kimberly Clark PFR95–270	Changes in subjects perception of odor strength using a Visual Analog Scale	No significant changes
			Changes in odor by sniffing the	No significant changes

Viscusi, 2009	Wavelength (nm): 254	N95-A	mask	
	Watts (W): 40	N95-B	Visual inspection for changes in physical appearance	No significant changes
	Duration (min): 30	N95-C		
	Dose (J/m ²): 3,520-3,620	SN95-D	Changes in odor by sniffing the mask	No significant changes
	Intensity (mW/cm ²): 0.18 to 0.20	SN95-E		
	Distance (cm): NR	SN95-F	Manual inspection for changes in 'feel' of the respirator (softness, pliability, coarseness, roughness, etc.).	No significant changes

Abbreviations: UVGI - Ultraviolet germicidal irradiation

Table C.2 – Fit

Author, Year	UVGI Intervention	N95 Masks	Method of Assessment of Changes in Fit	Changes following UVGI Exposure
Viscusi, 2011	Wavelength (nm): 245	3M 8000	Pre-UVGI Exposure: Standard eight exercise OSHA fit test protocol Post-UVGI Exposure: Multiple donning protocol using five exercises from the OSHA fit test protocol plus a final standard breathing exercise. The test subject repeated fit testing with the same FFR until accomplishing all five donnings without a strap breakage. Subjects repeated any test with a strap break, starting with a new FFR.	No significant reductions in fit
	Watts (W): 40	3M 8210		
	Duration (min): 30	Moldex 2200		
	Dose (J/m ²): 32,400	3M 1860		
	Intensity (mW/cm ²): 1.8	3M 1870		
	Distance (cm): NR	Kimberly Clark PFR95–270		
Bergman, 2011	Wavelength (nm): 245	3M 1860	Pre-UVGI Exposure: Standard eight exercise OSHA fit test protocol Post-UVGI Exposure: Multiple donning fit testing using a shortened 121 sec	Three cycles of UVGI did not cause significant changes in mask fit. The passing rate for the 3M 1860 was 95%, 100% and 100% after 1, 2 and 3 cycles respectively.
	Watts (W): 40	3M 1870		
	Duration (min): 15	KC PFR95-270 (46767)		
	Dose (J/m ²): 16,200			
	Intensity (mW/cm ²): 1.8			
	Distance (cm): NR			

PORTACOUNT protocol. The test used 6 exercises for 10 seconds each. Fit Factor was calculated as the ratio of the ambient particle concentration (sampled for 15 sec) divided by the mask concentration (sampled for 81 sec).

The passing rate for the 3M 1870 was 100% after 1, 2 and 3 cycles.

The passing rate for the KC PFR95-270 (46767) was 95%, 95% and 90% after 1, 2 and 3 cycles.

Abbreviations: FFR – filtering facemask respirator; OHSA - Occupational Safety and Health Administration; UVGI - Ultraviolet germicidal irradiation

Appendix D: Risk of Bias

Author, Year	Population: Masks evaluated from same lot to minimize any lot-to-lot variation	Design: Controlled study or pre-post design	Methodology: All evaluations performed in the same lab conditions	Outcome: evaluators blinded to study arm or outcome evaluated objectively (result provided by a machine)
Bergman, 2010	Yes	Yes	Not reported	Aerosol Penetration: Objective evaluation Airflow Resistance: Objective evaluation Physical Appearance: No
Bergman, 2011	Yes	Yes	Yes	Fit Testing: Objective evaluation Physical Appearance: No
Fisher, 2010	Not reported	Yes	Not reported	Decontamination: No
Heimbuch, 2011	Not reported	Yes	Similar conditions reported during the contamination process. Conditions during outcome measurement were not reported	Decontamination: No Physical Appearance: No
Lin, 2018	Not reported	Yes	Yes	Decontamination: No
Lindsley, 2015	Yes	Yes	Not reported	Aerosol Penetration: Objective evaluation Airflow Resistance: Objective evaluation
Lore, 2012	Not reported	Yes	Similar conditions reported during the contamination process. Conditions during outcome measurement were not reported	Aerosol Penetration: Objective evaluation Decontamination: No
Mills, 2018	Not reported	Yes	Yes	Decontamination: No
Viscusi, 2007	Yes	Yes	Yes	Aerosol penetration: Objective evaluation Physical Appearance: Objective evaluation
Viscusi, 2009	Yes	Yes	Yes	Aerosol Penetration: Objective evaluation Airflow Resistance: Objective evaluation Physical Appearance: No
Viscusi, 2011	Yes	Yes	Yes	Physical Appearance: No Fit: Subjects participating in the fit test were blinded, outcome assessors were not

Vo, 2009	Not reported	Yes	Not reported	Decontamination: No
Woo, 2012	Not reported	Yes	Yes	Decontamination: No
Abbreviations: UVGI - Ultraviolet germicidal irradiation
